

1

Method For Forming A MIM Capacitor

2

3

Background of Invention

4 1) Field of the Invention

5 This invention relates generally to fabrication of semiconductor devices
6 and more particularly to the fabrication of a MIM capacitor and conductive lines.

7

8 2) Description of the Prior Art

9 There are many types of capacitor structures for semiconductor
10 integrated circuits, such as metal-oxide-semiconductor (MOS) capacitors, PN junction
11 capacitors, and polysilicon-insulator-polysilicon (PIP) capacitors. Each of these capacitor
12 structures includes at least one monocrystalline silicon layer or polycrystalline silicon layer
13 which is used as a capacitor electrode. The use of silicon for the capacitor electrode,
14 however, may result in a higher electrode resistance than is desired.

15 It is thus desirable to reduce the resistance of capacitor electrodes to
16 decrease frequency dependence of the capacitor. Accordingly, metal-insulator-metal
17 (MIM) thin film capacitors have been developed to provide low electrode resistances.
18 Moreover, metal-insulator-metal capacitors can be used in integrated circuits requiring
19 high speed performance. In addition, metal-insulator-metal thin film capacitors have been
20 applied to advanced analog semiconductor devices because these capacitors have

1 capacitance fluctuation rates dependent on voltage and temperature which are sufficiently
2 low to provide desirable electrical characteristics.

3 In addition, there have been efforts to reduce thicknesses of dielectric
4 layers for integrated circuit capacitors to thereby increase the performance of capacitors
5 including these thinner dielectric layers. In particular, the capacitance of a capacitor can be
6 increased by reducing the thickness of the dielectric layer between the two electrodes of
7 the capacitor. There have also been efforts to increase capacitances by using dielectric
8 layers having relatively high dielectric constants, and by increasing the surface areas of the
9 capacitor electrodes. Furthermore, multi-wiring or multilevel interconnect processes have
10 been applied to semiconductor manufacturing methods to facilitate the development of
11 high-density integration and microelectronic technology.

12 Thus it is very necessary to provide a novel process of forming MIM
13 capacitors which can provide a new structure of the MIM capacitors having large
14 capacitance as well as high integration of the integrated circuit.

15 The inventors have found that with the standard CMOS technology
16 being applied in mixed signal and analog integrated circuits arena, more and more passive
17 elements are required for various applications. Due to its good performance and simplicity
18 of integration with CMOS technology, metal-insulator-metal {MIM} capacitor is widely
19 used for analog and RF purposes. However, due to its nature of backend processing, the
20 dielectric thickness used in MIM is much higher than poly-insulator-poly (PIP) and
21 polyinsulator-substrate (PIS) capacitors. This leads to lower specific capacitance

1 (capacitance per unit area) for MIM capacitor, When used for RF application, higher
2 specific capacitance, which means smaller area for a given capacitance value, becomes
3 more important when low coupling noise between the MIM and substrate is considered.
4 semiconductor.

5

6 The importance of overcoming the various deficiencies noted above is
7 evidenced by the extensive technological development directed to the subject, as
8 documented by the relevant patent and technical literature. The closest and apparently
9 more relevant technical developments in the patent literature can be gleaned by considering
10 US 6,387,750B1(Lai et al.) shows a process for a MIM capacitor.

Summary of the Invention

4 An embodiment of the present invention provides a method of
5 manufacturing a MIM capacitor which is characterized as follows.

6 We provide a semiconductor structure having a first region and a
7 capacitor region. Next we form a conductive layer over the semiconductor structure. The
8 first conductive layer is patterned to form a plurality of trenches in the capacitor region.
9 We form a capacitor dielectric layer over the first conductive layer. Next, we form a top
10 plate over the capacitor dielectric layer in the capacitor region to form a capacitor. The
11 first conductive layer in the first region is patterned to form conductive patterns and a
12 bottom plate. An interlevel dielectric layer is formed over the first conductive layer.

13 Additional objects and advantages of the invention will be set forth in
14 the description that follows, and in part will be obvious from the description, or may be
15 learned by practice of the invention. The objects and advantages of the invention may be
16 realized and obtained by means of instrumentalities and combinations particularly pointed
17 out in the append claims.

according to an embodiment of the invention.

1

2 **Detailed Description of the Preferred Embodiments**

3

4

5 It is to be understood and appreciated that the process steps and
6 structures described below do not cover a complete process flow. The present invention
7 can be practiced in conjunction with various integrated circuit fabrication techniques that
8 are used in the art, and only so much of the commonly practiced process steps are included
9 herein as are necessary to provide an understanding of the present invention.

10 The present invention will be described in detail with reference to the
11 accompanying drawings. It should be noted that the drawings are in greatly simplified
12 form and they are not drawn to scale. Moreover, dimensions have been exaggerated in
13 order to provide a clear illustration and understanding of the present invention.

14 An embodiment of a method of fabrication of a MIM capacitor and
15 conductive line is described as follows.

16 **A. Semiconductor structure and first conductive layer**

17 As shown in figure 1, we provide a semiconductor structure 100 having
18 a first region 124 and a capacitor region 122. The semiconductor structure can comprise,
19 but is not limited to a substrate having an insulating layer or layers and a conductive layer
20 or layers thereover. The substrate can be a substrate used in semiconductor manufacturing,

1 such as silicon wafer, GaAs substrate or SIO substrate. The top surface of the
2 semiconductor structure 100 is preferably a dielectric layer (e.g., IMD layer) and exposed
3 portions of a underlying conductive layer (interconnect layer n-2 or (n-2) metal layer).

4 A MIM capacitor will be subsequently formed in the capacitor region
5 122. Conductive patterns, such as wiring interconnects (e.g., metal lines, wiring layers
6 etc.), will be formed from the first conductive layer 104 in the first region 124.

7 As shown in figure 1, we form a conductive layer 104 over the
8 semiconductor structure.

9 The first conductive layer 104 is preferably comprise of alloys of Al,
10 Cu, Ti, Ta, etc. and preferably has a thickness in the range of between 3000 and 10000 Å
11 (angstrom).

12 The first conductive layer 104 will be formed into at least a bottom
13 plate for a capacitor and preferably a n-1 level conductive interconnect layer (e.g., n-1
14 metal layer or wiring layer).

15

16 **B. pattern the first conductive layer 104 to form a plurality of**
17 **trenches**

18 Referring to figures 2, 3A and 3B, we pattern the first conductive layer
19 104 to form a plurality of trenches 114 in the capacitor region 122. The trenches increase

1 the capacitance area for the subsequently formed MIM capacitor. Preferably trenches are
2 only formed in the capacitor region 122.

3 To create the plurality of trenches 114, preferably first, we form a trench
4 resist layer 110 over the first conductive layer 104 as shown in figure 2. The trench resist
5 layer has openings 108 that define areas where trenches will be formed in the capacitor
6 area.

7 As shown in figure 3A, trenches 114 are etched using the trench resist
8 layer 110 as an etch mask. The trenches are preferably only etched in the capacitor region
9 122. Preferably the trench resist layer has no opening in the first region. The resist layer is
10 removed.

11 The trenches preferably have a Depth (D) between 2400 and 8000 Å of
12 the first conductive layer 104. The trenches extend down into the conductive layer between
13 24% and 80% of the thickness of the conductive layer 104. The trenches have a width W
14 between 2000Å and 10000Å, depending on the technology used. The larger dimension in
15 D and smaller dimension in W, give a bigger gain in capacitance value.

16 Preferably as shown figure 3B, the plurality of trenches is formed in a
17 pattern of rows and columns (e.g., checkerboard) in the capacitor region. That is the
18 trenches are lined up in a grid pattern as shown in figure 3B. The plurality of trench forms
19 a “sea of trenches”. The smaller the spacing between the trenches in figure 3B, the larger
20 gain the capacitance. Its limit depends on how advance the technology used. For example,
21 current industry leading-edge 0.13um technology node presents a limit of about 0.2um

1 space. For less advanced technology, the space limit can't be as small as 0.2um. It might be
2 looser, say about 0.3um for 0.18um technology node. The larger dimension in Depth D and
3 smaller the spacing and width of sea of trenches, the higher density of the trenches.
4 Therefore, the bigger gain in capacitance value.

5 **C. form a capacitor dielectric layer 118**

6 As shown in figure 4, we form a capacitor dielectric layer 118 over the
7 first conductive layer 104. The capacitor dielectric layer 118 preferably has a thickness
8 between 100 and 1000 Å and is preferably comprised of silicon oxide, silicon nitride,
9 silicon oxide-nitride, and tantalum oxide. The dielectric layer can be formed by plasma
10 enhanced chemical vapor deposition. The thickness of the dielectric layer depends on how
11 electrical dielectric strength required. A higher dielectric strength requires a thicker
12 dielectric layer.

13

14 **D. form a top plate 120**

15 Referring to figures 5 and 6, we form a top plate 120A over the
16 capacitor dielectric layer 118 in the capacitor region 122.

17 The top plate 120 is preferably formed by forming a top plate layer 120
18 over the capacitor dielectric layer 120. Then we mask and pattern the top plate layer 120
19 preferably using a resist and etch process.

1 The top plate 120A preferably has a thickness between 700 and 1500 Å
2 and is preferably comprise of TiN, Cu, or Al alloy.

3

4 ***E. pattern the first conductive layer in the first region to form***
5 ***conductive patterns 104L***

6 Referring to figures 7 and 8, next we patterned the first conductive layer
7 in the first region 124 to form conductive patterns 104L (e.g., metal lines or interconnects)
8 and a bottom plate 104B. First, as shown in figure 7, we form a bottom metal resist mask
9 128 over the first conductive layer. The bottom metal resist mask 128 has openings 136
10 that define the interconnect lines and patterns (e.g., N-1 metal-interconnect layer). As
11 shown in figure 8, we etch the first conductive layer using the bottom metal resist mask
12 128 as an etch mask. This forms to form conductive patterns 104L (e.g., metal lines or
13 interconnects) and a bottom plate 104B. The mask is then removed.

14 The embodiment's single step of patterning the first conductive layer to
15 form line patterns 104L (after the etch trenches in the first conductive layer) is important
16 because the embodiment patterning step is more accuracy and manufacturable.

17 A MIM capacitor 121 is formed in the capacitor region 122. The MIM
18 capacitor is comprised of : the top plate 120A, capacitor dielectric 118 and the bottom plate
19 104B.

20

1 **F. form an interlevel dielectric layer 144**

2 As shown in figure 9, we form an interlevel dielectric layer 144 over the
3 first conductive layer. The interlevel dielectric layer 144 is preferably formed of high
4 density plasma enhanced chemical vapor silicon oxide deposition combined with plasma
5 enhanced TEOS (tetraethyl orthosilicate). The interlevel dielectric layer is preferably
6 planarized using chemical-mechanical polishing (CMP) process.

7 Preferably, the interlevel dielectric layer 144 is used to insulate
8 between the adjacent metal layers 104L (n-1 level) and 130 ((fig 10,) n-level metal).

9 **G. form interconnects 124A 124B 124C 130A 130B 130C to**
10 **contact the top plate 120, the bottom plate 104 and the**
11 **conductive patterns 104L**

12 Next we form interconnects 124A 124B 124C 130A 130B 130C to
13 contact the top plate 120, the bottom plate 104 and the conductive patterns 104L. The
14 capacitor top plate interconnects 124A 130A contact the capacitor top plate 120. The
15 capacitor bottom plate interconnect 104B contact the capacitor bottom plate 104B. The
16 line interconnects 130C contact the conductive patterns 104L.

17 Preferably as shown in figure 10, we form via contacts 124A 124B
18 124C in the interlevel dielectric layer 144 to contact the top plate 120, the bottom plate 104
19 and the conductive patterns 104L.

1 Next we form a second conductive layer 120A 130B 130C over the
2 interlevel dielectric layer 144 and the via contacts 124A 124B 124C. The second
3 conductive layer is preferably the n level conductive wiring layer or n level interconnect.

4

5 It is possible to use other interconnect process to contact the top plate
6 120, the bottom plate 104 and the conductive patterns 104L.

7

8

9 **H. *benefits***

10 Embodiments of the invention provide a process of forming a three
11 dimensional MIM capacitor with increased capacitance. The embodiment has a lower
12 coupling noise between the MIM and the substrate.

13 The embodiments of the invention provide a three dimensional MIM
14 capacitor which can effectively upgrade the integration of integrated circuits.

15

16 Importantly, the embodiments pattern the wiring layer in separate
17 subsequent steps than the etch steps to form trenches in the bottom plate. Specifically, the
18 invention does not etch the (bottom plate) trenches in the first region 124 when the bottom
19 plate trenches 114 in the capacitor region 122 are etched. See figure 3A. This is an

1 significant advantage because the embodiment's single etch process to pattern the lines 104
2 L (Fig 8) is more precise, simpler and more manufacturability than a double etch process.

3 The bottom interconnects 104L in non-MIM area 124 are not affected
4 by MIM trench 114 patterning and etch process (See figures 2 and 3A).

5

6

7 In the above description numerous specific details are set forth such as
8 thicknesses, etc., in order to provide a more thorough understanding of the present
9 invention. It will be obvious, however, to one skilled in the art that the present invention
10 may be practiced without these details. In other instances, well known process have not
11 been described in detail in order to not unnecessarily obscure the present invention.

12 Although this invention has been described relative to specific
13 insulating materials, conductive materials and apparatuses for depositing and etching these
14 materials, it is not limited to the specific materials or apparatuses but only to their specific
15 characteristics, such as conformal and nonconformal, and capabilities, such as depositing
16 and etching, and other materials and apparatus can be substituted as is well understood by
17 those skilled in the microelectronics arts after appreciating the present invention

18

19 While the invention has been particularly shown and described with
20 reference to the preferred embodiments thereof, it will be understood by those skilled in
21 the art that various changes in form and details may be made without departing from the

1 spirit and scope of the invention. It is intended to cover various modifications and similar
2 arrangements and procedures, and the scope of the appended claims therefore should be
3 accorded the broadest interpretation so as to encompass all such modifications and similar
4 arrangements and procedures.

5
